PRODUCT DESCRIPTION

Carapace® EMP110 has been used in the high volume production of PCBs since 1987. The Carapace® family has been formulated to exceed the increasing demands of PCB processes, combined with a large process window.

- High resistance to low solids fluxes.
- Electroless Nickel / immersion gold compatibility.
- Fine solder dam resolution (50-75µm, 2-3 mil).
- Fast processing times allowing High throughput and productivity.
- Low ionic contamination.
- Solderball elimination.
- Optimised rheological and coating properties for each method of application.
- High moisture and insulation resistance.
- Excellent adhesion to flexible substrates.
- Contains no halogenated flame retardants.

Carapace® EMP110 is a contact exposure, aqueous developing, liquid photoimageable soldermask, using two-component epoxy technology to give high levels of chemical resistance over copper, copper oxide, tin-lead or gold plated circuits. Due to their resolution capability, high dielectric strength and physical resistance properties Carapace® soldermasks are used as solder resists and insulation coverings on all types of printed circuits, particularly high-reliability, double-sided and multilayer, fine line, surface mount boards.
CARAPACE® EMP110 PRODUCT RANGE

PASTES:
All Carapace® pastes are coded as EMP110 followed by a 4-figure number and letters. The 4-figure number and letters denote the colour, finish and application method.

E.g. EMP110/1972 DGM AS

Carapace® EMP110 pastes are available as standard in the following colours, finishes and application methods:

- Light Green Matt
- Light Green Gloss
- Light Green Extra Matt
- Dark Green Matt
- Dark Green Gloss
- Blue Gloss
- Blue Matt
- Red Gloss
- Red Matt
- Black
- White
- Yellow Matt
- Yellow/Green Matt
- Yellow/Green Gloss
- Transparent

Products for application methods that are not listed may be available upon request.

HARDENERS:

1) H1123 - Standard (not suitable for electroless Ni – immersion Au (ENIG).
2) H-1348 - High chemical resistance specifically formulated for ENIG.
3) H-2010 - Hard drying (suitable for ENIG see pg.7).
4) EMP110 PtB - The following hardeners are grouped into the EMP110 PtB class:
   b) H-1833 - Hard drying, reduced Cu tarnish, TGIC-free (can be used with ENIG see pg.7).
   c) H-1400 - Fast drying reduced copper tarnish hardener (not suitable for ENIG).
   d) H-1550 - Fast drying hardener (not suitable for ENIG).
Board surface preparation:
Copper surfaces should be mechanically or chemically cleaned to give a 60s waterbreak-free surface. Recommended mechanical methods are pumice, aluminium oxide or 320 grit brush.

Tin/lead boards should be thoroughly degreased using detergent/water rinse or solvent cleaning methods. Adhesion over tin/lead will be enhanced by lightly brushing the surface prior to coating.

All boards must be completely dry before coating.

Mixing:
Carapace® is supplied pre-weighed in 1kg, 3kg or 10kg packs.

The resist should be mixed in the ratio 100 parts paste (pt A) to 19 parts hardener by weight. Stir well to ensure complete mixing.

Incomplete mixing can cause poor developing, stickiness during exposure and impaired final properties.

Viscosity reduction:

SP formulations:
SP versions of EMP110 are supplied screen ready. If viscosity adjustment is required prior to, or during printing, then this may be achieved using Electrareducer ER1. No more than 5% reducer should be added or deterioration of the printing and drying properties may occur, resulting in thin deposits on track edges and/or prolonged drying times.

CC, ES and AS formulations:
It is advisable to use a slow speed mechanical mixer when mixing in solvent for CC, AS, ES. Care should be taken to avoid incorporating air into the resist during mixing. Resist should be allowed to stand for 2 hours after mixing to allow air to escape. Excessive air in resist can cause microbubbles/voids in the finished film and/or poor curtain stability when curtain-coating.

CC:
EMP110 CC soldermasks should be reduced to a viscosity of 80 to 100s (Ford Nº4 cup), 60 to 80s (Frikmar Nº4) at 25°C with Electrareducer ER6. Where ER6 is not available, an equivalent from an approved source may be used. The use of non-approved solvents is not recommended as they can cause contamination and other processing problems. The amount required is typically 30 to 35% by weight.

When using curtain-coating equipment that utilises short/low temperature evaporation zones it is advantageous to use a blend of viscosity reducers to ensure microbubble elimination. Recommendations will be made by the Electra Technical Service Department during pre-trial discussions.

ES:
EMP110 ES soldermasks should be reduced to a viscosity of 70 to100s (Ford Nº4 cup), 60 to 80s (Frikmar Nº4) with Electrareducer ER10. Where ER10 is not available, an equivalent from an approved source may be used. The use of non-approved solvents is not recommended as they can cause contamination and other processing problems. The amount required is typically 30 to 35% by weight.
EMP110 AS soldermasks should be reduced with Electreducer ER10. Where ER10 is not available, an equivalent from an approved source may be used. The use of non-approved solvents is not recommended as they can cause contamination and other processing problems. Addition level required will depend on spray system used. The following levels are typical:

<table>
<thead>
<tr>
<th>Machine type</th>
<th>% reducer (by weight)</th>
<th>Viscosity</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Zahn Nº3</td>
</tr>
<tr>
<td>Argus horizontal spray</td>
<td>35 to 45%</td>
<td>25 to 30s</td>
</tr>
<tr>
<td>Teledyne vertical spray</td>
<td>35 to 50%</td>
<td>25 to 30s</td>
</tr>
</tbody>
</table>

Due to the fast viscosity readings using a Zahn Nº3 cup, air inclusion can give erratic readings. It is therefore recommended to use the Ford Nº4 or a cup giving similar values (e.g. Frikmar Nº4).

**Process settings:**

**SP:**
Mesh count: 37-55T polyester.
Squeegee: 60-70 Shore.

20µm dry thickness should be aimed for; this is typically achieved using a 43T.

The board outline image may be made on the screen using conventional stencil material or masking tape and screen filler. To prevent a build up of ink on the reverse of the screen that may block holes, it is advisable to shift alternate boards along the x- or y-axis before printing. Alternatively, a rudimentary stencil, such as an expanded drill mask, can be used on the screen to prevent ink going into the holes.

Do **not** utilise the vacuum bed, as this will suck an exaggerated amount of ink into the holes.

**CC:**
The exact coating parameters required to give optimum results should be determined by preliminary tests using typical board designs. Viscosity and coating speed can vary depending on the track-height, density and sidewall configuration.

Below are recommended settings for initial set-up:

- Nip-gap 0.3 to 0.6mm
- Coating speed 90 to 100 mmin⁻¹
- Viscosity 70 to 100s Ford Nº4 cup
- Wet-weight 80 to 110gm⁻² depending on track-height and density
- Pump rate Set to attain desired wet film weight

Increasing or decreasing pump rate is a quick and precise way of adjusting the wet-weight. Changing coating speed will also vary the wet-weight, however it is advisable not to go below 80mmin⁻¹ (causing ink to be dragged onto belt and exaggeration of tear-drops) or exceeding 120mmin⁻¹ (increasing risk of skips and shadowing).
**ES:** Exact spray parameters will depend on track height and circuit layout. These parameters will also depend on equipment manufacturer, please contact Electra Technical Service Department for specific recommendations.

Below are recommended settings for the initial set-up:

Conveyor: 1.0 to 2.0 m/min

Potential: 25 to 40 kV

The potential required will depend on the board design. Boards with a higher track density will need a higher potential, similarly boards with large laminate areas will generally require lower potentials.

Viscosity: 70 to 100 s Ford No. 4 cup.

Rotating bell speed: 25,000 to 35,000 rpm (where applicable).

<table>
<thead>
<tr>

<tr>
<td></td>
<td>Reduced thinning on track-edges</td>
<td>Increased risk of resist thinning on track-edges</td>
</tr>
<tr>
<td></td>
<td>but increased risk of orange-peel</td>
<td></td>
</tr>
</tbody>
</table>

**AS:** Exact spray parameters will depend on track height and circuit layout. These parameters will also depend on equipment manufacturer, please contact Electra Technical Service Department for specific recommendations.

Below are general recommendations and guidelines:

Wet-weight: 60 to 100 µm (1.2 to 4 mils)

Tank pressure and coating speed are set to give desired wet thickness. Atomising pressure should be set to give minimal mottling. Shaping air is to be adjusted to give an even spray pattern.

Lower atomising pressures and higher coating speeds will lead to increased mottling.

**Tack-dry:**
The aim of the tack-drying stage is to solely remove the solvents. It is important for the drying chamber (static or conveyorised) to have good air circulation with air supply and extraction facilities.

IR Drying
IR drying is dependent on coating application method, IR wave-length and IR intensity. Please contact Electra Technical Support Department for recommendations regarding specific equipment types and manufacturers.

Optimum board temperature: 125 to 135°C. Peak temperature
Optimum drying time: 4 to 5 minutes

Exposure
Step wedge: 9-12 clear (Stouffer 21 step).
Note: exact milliJoule requirements will vary with formulation type.

Determination of the correct exposure should be carried out after setting the developing speed since this will affect the step wedge reading obtained.

Step wedge checks should be carried out on brushed copper with the step wedge under the phototool. Energy level should be measured through the artwork and mylar/glass. It is important to recognise that the energy level should only be used as a guide for setting the correct exposure; step wedges should be used for determining the actual exposure setting. Separate exposure tests should be carried out for each different colour, as variations in lamp emissions can cause differences in exposure speed. After determining the correct setting, energy level can be monitored as a means to check for any changes in lamp output.
Developing

Developer: 1% soln sodium or potassium carbonate.
Spray pressure: 1.5-2.5 kgcm⁻², 20-40 psi.
Spray time: 30-90s in carbonate chamber(s) (dependent on quantity of ink in holes).
Temperature: 35 to 40°C for H-1613 and H-1833
30 to 32°C for all other hardeners

Boards should be well rinsed with fresh water and fully dried after developing. Do not final cure boards when wet.

The optimum developing speed is set when an unexposed board develops off completely, 25-50% of the way through the machine. This speed should be ascertained by preliminary tests prior to making exposure tests.

Developing speed and break-point settings will be determined by the amount of ink deposited in the holes during coating.

Due to the varying degree of ink deposited in holes, different application methods will require different developing speeds.

Typical developing speeds using a 2m long carbonate chamber:

- Screen-print: 1.3 to 2.0 mmin⁻¹
- Curtain-coating: 2.0 to 2.5 mmin⁻¹
- Air-spray: 3.0 to 4.0 mmin⁻¹

Final Cure

Convection oven: 60 mins at 150°C

Electroless nickel – immersion gold (ENIG)

Thin coating and/or overcuring of the soldermask can lead to adhesion loss after ENIG. Coating thickness should not fall below 10µm (0.4mils) and cure cycles must not exceed the recommended time and temperature. If coating thickness is low due to track heights or via holes then it is recommended to carry out a two-stage cure cycle as follows:

1) Final Cure: 10-15 mins at 150°C
2) ENIG plate
3) Recure: 45-60 mins at 150°C

Note: the two-stage cure process is particularly recommended with H1833 hardener or if using a chemical clean process prior to soldermask.

UV bumping

It is not normally necessary to UV cure Carapace EMP110 but under certain conditions it may be advantageous (see below). Under these conditions, conveyor speeds should be set to attain 1500 to 2000 mJcm⁻².
High film weight plating:
When depositing high filmweights and/or coating heavily plated tracks it is sometimes possible to see slight wrinkling of the soldermask between the tracks after final cure. UV curing before final cure may prevent this.

Flux residues/staining:
Occasionally flux residues or staining can be seen on boards, particularly after Hot Air Solder Levelling with very acidic or aggressive fluxes. Washing boards when still hot causes this and can be exaggerated by using hot water rinse. Boards must be allowed to cool after soldering before rinsing and it is recommended all rinse solutions be below 40°C (104°F).

If staining does occur it can be removed by post baking boards, after soldering, for 10-15 mins @ 120-150°C. Alternatively if it is not possible to cool boards after HASL, staining can be prevented by giving boards a UV bump cure after the final thermal cure.

Reduced ionic contamination:
Certain fluxes, in conjunction with a poor recirculated-rinse after HASL, can lead to increased levels of ionic contamination. Although Carapace® has proven to give very low contamination figures, in these extreme cases a UV bump after final cure will reduce the risk of increased levels.

Reduced soldermask outgassing:
Where important soldermask outgassing can be reduced by a post-cure UV bump (see page 10).

Via hole plugging
Carapace® EMP110 can be used for reliable via-hole plugging during the initial soldermask print stage. In order to achieve 100% of holes plugged it is advisable to use a double print stroke.

In order to avoid splitting or blistering of the vias please note the following:

Tack-dry: Minimum of 40mins at 80°C
Exposure: Minimum clear 12 using Stouffer 21-step wedge
Developing: Minimum speed to ensure required holes wash clean

If the board design requires prolonged developing times due to small hole development it is recommended boards are given a pre-bake after developing before final cure to allow slow release of any trapped moisture from vias.

Although it is not recommended to UV bump before final cure, it is advisable to pre-bake boards prior to passing through the UV curer if utilising a UV bump at this stage.

Pre-bake: 15 to 30 mins at 70 to 80°C

Safelight
It is not normally necessary to print Carapace® EMP110 under safelight conditions, although it may be advisable if there are long delays before drying. Between drying/exposing and exposing/developing, boards should be kept in yellow light. Boards should, in any case, be kept out of direct sunlight until completely processed.

Notation/markings inks
Both UV and thermal curing notation inks are suitable for use with Carapace® EMP110. Thermal curing inks may be applied before or after final cure. If UV curing notation inks are used they should be applied before final cure and before UV bump if this is used. In this case UV curing the notation ink will serve as the bump for the soldermask.
Stripping
After developing, any reject boards may be stripped of soldermask using a 5% NaOH solution at 40-50°C

After curing, soldermask can be stripped using a proprietary soldermask stripper such as ES108H.

Cleaning
Equipment should be cleaned of residual soldermask using SW100 or Dowanol PMA.

Shelf-life
Minimum 9 months* from date of manufacture when stored in cool, dry, recommended conditions. Storage should be between 10 and 25°C and must be away from sources of heat and direct sunlight.

*H-1613 has a minimum shelf-life of 12 months from date of manufacture.
